Poisson Approximation

Binomial Approximation to the Poisson

If X_1, X_2, \ldots, X_n are i.i.d. Bernoulli random variables with parameter $\frac{\lambda}{n}$, then for large n, the distribution of their sum is close to a Poisson distribution with parameter λ : $S_n \triangleq \sum_{i=1}^n X_i \approx \text{Po}(\lambda)$.

Poisson Approximation

Binomial Approximation to the Poisson

If X_1, X_2, \ldots, X_n are i.i.d. Bernoulli random variables with parameter $\frac{\lambda}{n}$, then for large n, the distribution of their sum is close to a Poisson distribution with parameter λ : $S_n \triangleq \sum_{i=1}^n X_i \approx \text{Po}(\lambda)$.

General Poisson Approximation (Law of Small Numbers)

For random variables $\{X_i\}_{i=1}^n$ on $\mathbb{N}_0 \triangleq \{0, 1, \ldots\}$, the sum $\sum_{i=1}^n X_i$ is approximately Poisson distributed with mean $\lambda = \sum_{i=1}^n p_i$ as long as

- $\mathbb{P}(X_i = 0)$ is close to 1,
- $\mathbb{P}(X_i = 1)$ is uniformly small,
- $\mathbb{P}(X_i > 1)$ is negligible as compared to $\mathbb{P}(X_i = 1)$,
- $\{X_i\}_{i=1}^n$ are weakly dependent.

Information-Theoretic Results for Poisson Approximation

Maximum Entropy Result for Poisson Approximation

The $Po(\lambda)$ distribution has maximum entropy among all probability distributions that can be obtained as sums of independent Bernoulli RVs:

$$\begin{split} H(\mathsf{Po}(\lambda)) &= \sup_{S \in B_{\infty}(\lambda)} H(S) \\ B_{\infty}(\lambda) &\triangleq \bigcup_{n \in \mathbb{N}} B_{n}(\lambda) \\ B_{n}(\lambda) &\triangleq \left\{ S : S = \sum_{i=1}^{n} X_{i}, \ X_{i} \sim \mathsf{Bern}(p_{i}) \text{ independent}, \ \sum_{i=1}^{n} p_{i} = \lambda \right\}. \end{split}$$

Information-Theoretic Results for Poisson Approximation

Maximum Entropy Result for Poisson Approximation

The $Po(\lambda)$ distribution has maximum entropy among all probability distributions that can be obtained as sums of independent Bernoulli RVs:

$$\begin{split} H(\mathsf{Po}(\lambda)) &= \sup_{S \in B_{\infty}(\lambda)} H(S) \\ B_{\infty}(\lambda) &\triangleq \bigcup_{n \in \mathbb{N}} B_{n}(\lambda) \\ B_{n}(\lambda) &\triangleq \left\{ S : S = \sum_{i=1}^{n} X_{i}, \ X_{i} \sim \mathsf{Bern}(p_{i}) \text{ independent}, \ \sum_{i=1}^{n} p_{i} = \lambda \right\}. \end{split}$$

Due to a monotonicity property, then

$$H(\mathsf{Po}(\lambda)) = \lim_{n \to \infty} \sup_{S \in B_n(\lambda)} H(S).$$

Maximum Entropy Result for Poisson Approximation (Cont.) For $n \in \mathbb{N}$, the maximum entropy distribution in the class $B_n(\lambda)$ is Binomial $\left(n, \frac{\lambda}{n}\right)$, so

$$H(\mathsf{Po}(\lambda)) = \lim_{n \to \infty} H\left(\mathsf{Binomial}\left(n, \frac{\lambda}{n}\right)\right).$$

Information-Theoretic Ideas in Poisson Approximation

Nice surveys on the information-theoretic approach for Poisson approximation are available at:

- I. Kontoyiannis, P. Harremoës, O. Johnson and M. Madiman, "Information-theoretic ideas in Poisson approximation and concentration," slides of a short course (the slides are available at the homepage of I. Kontoyiannis), September 2006.
- O. Johnson, Information Theory and the Central Limit Theorem, Imperial College Press, 2004.

Total Variation Distance

Let P and Q be two probability measures defined on a set $\mathcal{X}.$ Then, the total variation distance between P and Q is defined by

$$d_{\mathsf{TV}}(P,Q) \triangleq \sup_{\mathsf{Borel}\,A \subseteq \mathcal{X}} |P(A) - Q(A)|$$

where the supermum is taken w.r.t. all the Borel subsets A of \mathcal{X} .

4 15 16 16 15

Total Variation Distance

Let P and Q be two probability measures defined on a set $\mathcal{X}.$ Then, the total variation distance between P and Q is defined by

$$d_{\mathsf{TV}}(P,Q) \triangleq \sup_{\mathsf{Borel}\,A \subseteq \mathcal{X}} |P(A) - Q(A)|$$

where the supermum is taken w.r.t. all the Borel subsets A of \mathcal{X} . If \mathcal{X} is a countable set then this definition is simplified to

$$d_{\mathsf{TV}}(P,Q) = \frac{1}{2} \sum_{x \in \mathcal{X}} |P(x) - Q(x)| = \frac{||P - Q||_1}{2}$$

so the total variation distance is equal to one-half of the L_1 -distance between the two probability distributions.

Total Variation Distance

Let P and Q be two probability measures defined on a set $\mathcal{X}.$ Then, the total variation distance between P and Q is defined by

$$d_{\mathsf{TV}}(P,Q) \triangleq \sup_{\mathsf{Borel}\,A \subseteq \mathcal{X}} |P(A) - Q(A)|$$

where the supermum is taken w.r.t. all the Borel subsets A of \mathcal{X} . If \mathcal{X} is a countable set then this definition is simplified to

$$d_{\mathsf{TV}}(P,Q) = \frac{1}{2} \sum_{x \in \mathcal{X}} |P(x) - Q(x)| = \frac{||P - Q||_1}{2}$$

so the total variation distance is equal to one-half of the L_1 -distance between the two probability distributions.

<u>Question</u>: How to get bounds on the total variation distance and the entropy difference for the Poisson approximation ?

A (10) A (10)

Chen-Stein Method

The Chen-Stein method forms a powerful probabilistic tool to calculate error bounds for the Poisson approximation (Chen 1975).

This method is based on the simple property of the Poisson distribution where $Z \sim Po(\lambda)$ with $\lambda \in (0, \infty)$ if and only if

$$\lambda \mathbb{E}[f(Z+1)] - \mathbb{E}[Z f(Z)] = 0$$

for all bounded functions f that are defined on $\mathbb{N}_0 \triangleq \{0, 1, \ldots\}$.

• • = • • = •

Chen-Stein Method

The Chen-Stein method forms a powerful probabilistic tool to calculate error bounds for the Poisson approximation (Chen 1975).

This method is based on the simple property of the Poisson distribution where $Z \sim Po(\lambda)$ with $\lambda \in (0, \infty)$ if and only if

$$\lambda \mathbb{E}[f(Z+1)] - \mathbb{E}[Z f(Z)] = 0$$

for all bounded functions f that are defined on $\mathbb{N}_0 \triangleq \{0, 1, \ldots\}$.

This method provides a rigorous analytical treatment, via error bounds, to the case where W has approximately a Poisson distribution $Po(\lambda)$. The idea behind this method is to treat analytically (by bounds)

$$\lambda \mathbb{E}[f(W+1)] - \mathbb{E}[W f(W)]$$

which is shown to be close to zero for a function f as above.

・ロン ・四 ・ ・ ヨン

The following theorem relies on the Chen-Stein method:

Bounds on the Total Variation Distance for Poisson Approximation, [Barbour & Hall, 1984]

Let $W = \sum_{i=1}^{n} X_i$ be a sum of n independent Bernoulli random variables with $\mathbb{E}(X_i) = p_i$ for $i \in \{1, \ldots, n\}$, and $\mathbb{E}(W) = \lambda$. Then, the total variation distance between the probability distribution of W and the Poisson distribution with mean λ satisfies

$$\frac{1}{32} \left(1 \wedge \frac{1}{\lambda} \right) \sum_{i=1}^{n} p_i^2 \le d_{\mathsf{TV}}(P_W, \mathsf{Po}(\lambda)) \le \left(\frac{1 - e^{-\lambda}}{\lambda} \right) \sum_{i=1}^{n} p_i^2$$

where $a \wedge b \triangleq \min\{a, b\}$ for every $a, b \in \mathbb{R}$.

Generalization of the Upper Bound on the Total Variation Distance for a Sum of Dependent Bernoulli Random Variables

Let I be a countable index set, and for $\alpha \in I,$ let X_α be a Bernoulli random variable with

$$p_{\alpha} \triangleq \mathbb{P}(X_{\alpha} = 1) = 1 - \mathbb{P}(X_{\alpha} = 0) > 0.$$

Let

$$W \triangleq \sum_{\alpha \in I} X_{\alpha}, \quad \lambda \triangleq \mathbb{E}(W) = \sum_{\alpha \in I} p_{\alpha}$$

where it is assumed that $\lambda \in (0, \infty)$. Note that W is a sum of (possibly dependent and non-identically distributed) Bernoulli RVs $\{X_{\alpha}\}_{\alpha \in I}$.

< 回 > < 三 > < 三 >

Generalization of the Upper Bound on the Total Variation Distance for a Sum of Dependent Bernoulli Random Variables

Let I be a countable index set, and for $\alpha \in I,$ let X_α be a Bernoulli random variable with

$$p_{\alpha} \triangleq \mathbb{P}(X_{\alpha} = 1) = 1 - \mathbb{P}(X_{\alpha} = 0) > 0.$$

Let

$$W \triangleq \sum_{\alpha \in I} X_{\alpha}, \quad \lambda \triangleq \mathbb{E}(W) = \sum_{\alpha \in I} p_{\alpha}$$

where it is assumed that $\lambda \in (0, \infty)$. Note that W is a sum of (possibly dependent and non-identically distributed) Bernoulli RVs $\{X_{\alpha}\}_{\alpha \in I}$.

For every $\alpha \in I$, let B_{α} be a subset of I that is chosen such that $\alpha \in B_{\alpha}$. This subset is interpreted [Arratia et al., 1989] as the neighborhood of dependence for α where X_{α} is independent or weakly dependent of all of the X_{β} for $\beta \notin B_{\alpha}$.

Furthermore, the following coefficients were defined by [Arratia et al., 1989]:

$$b_{1} \triangleq \sum_{\alpha \in I} \sum_{\beta \in B_{\alpha}} p_{\alpha} p_{\beta}$$

$$b_{2} \triangleq \sum_{\alpha \in I} \sum_{\alpha \neq \beta \in B_{\alpha}} p_{\alpha,\beta}, \quad p_{\alpha,\beta} \triangleq \mathbb{E}(X_{\alpha} X_{\beta})$$

$$b_{3} \triangleq \sum_{\alpha \in I} s_{\alpha}, \quad s_{\alpha} \triangleq \mathbb{E} |\mathbb{E}(X_{\alpha} - p_{\alpha} | \sigma(\{X_{\beta}\})_{\beta \in I \setminus B_{\alpha}})|$$

where $\sigma(\cdot)$ in the conditioning of last equality denotes the σ -algebra that is generated by the random variables inside the parenthesis.

Then, the following upper bound on the total variation distance holds:

$$d_{\mathsf{TV}}(P_W, \mathsf{Po}(\lambda)) \le (b_1 + b_2) \left(\frac{1 - e^{-\lambda}}{\lambda}\right) + b_3 \left(1 \wedge \frac{1.4}{\sqrt{\lambda}}\right).$$

3

同下 (三下 (三)

Then, the following upper bound on the total variation distance holds:

$$d_{\mathsf{TV}}(P_W, \mathsf{Po}(\lambda)) \le (b_1 + b_2) \left(\frac{1 - e^{-\lambda}}{\lambda}\right) + b_3 \left(1 \wedge \frac{1.4}{\sqrt{\lambda}}\right).$$

Proof Methodology: The Chen-Stein method [Arratia et al., 1989].

3

< 同 ト く ヨ ト く ヨ ト

Then, the following upper bound on the total variation distance holds:

$$d_{\mathsf{TV}}(P_W, \mathsf{Po}(\lambda)) \le (b_1 + b_2) \left(\frac{1 - e^{-\lambda}}{\lambda}\right) + b_3 \left(1 \wedge \frac{1.4}{\sqrt{\lambda}}\right).$$

Proof Methodology: The Chen-Stein method [Arratia et al., 1989].

Special Case

If $\{X_{\alpha}\}_{\alpha \in I}$ are independent and $\alpha \triangleq \{1, \ldots, n\}$, then $b_1 = \sum_{i=1}^n p_i^2$ and $b_2 = b_3 = 0$, which gives the previous upper bound on the total variation distance.

 $\Rightarrow p_i = \frac{\lambda}{n}$ for all $i \in \{1, ..., n\}$ (i.e., a sum of n i.i.d. Bernoulli random variables with parameter $\frac{\lambda}{n}$) gives that

$$d_{\mathsf{TV}}(P_W, \mathsf{Po}(\lambda)) \le \frac{\lambda^2}{n} \searrow 0.$$

An upper bound on the total variation distance between W and the Poisson random variable $Z \sim Po(\lambda)$ was introduced. This bound was derived by Arratia et al. (1989) via the Chen-Stein method.

An upper bound on the total variation distance between W and the Poisson random variable $Z \sim Po(\lambda)$ was introduced. This bound was derived by Arratia et al. (1989) via the Chen-Stein method.

Question 1

Does a small total variation distance between two probability distributions ensure that their entropies are also close ?

< ∃ > <

Question 1

Does a small total variation distance between two probability distributions ensure that their entropies are also close ?

Answer 1

Answer: In general, NO. The total variation distance between two probability distributions may be arbitrarily small whereas the difference between the two entropies is arbitrarily large.

• • = • • = •

Question 1

Does a small total variation distance between two probability distributions ensure that their entropies are also close ?

Answer 1

Answer: In general, NO. The total variation distance between two probability distributions may be arbitrarily small whereas the difference between the two entropies is arbitrarily large.

A Possible Example [Ho & Yeung, ISIT 2007]

For a fixed $L \in \mathbb{N}$, let $P = (p_1, p_2, \dots, p_L)$ be a probability mass function. For $M \ge L$, let

$$Q = \left(p_1 - \frac{p_1}{\sqrt{\log M}}, p_2 + \frac{p_1}{M\sqrt{\log M}}, \dots, p_L + \frac{p_1}{M\sqrt{\log M}}, \frac{p_1}{M\sqrt{\log M}}, \dots, \frac{p_1}{M\sqrt{\log M}}\right).$$

Example (cont.)

Then

$$d_{\mathsf{TV}}(P,Q) = \frac{2\,p_1}{\sqrt{\log M}} \searrow 0$$

when $M \to \infty.$ On the other hand, for a sufficiently large M,

$$H(Q) - H(P) \approx p_1 \left(1 - \frac{L}{M}\right) \sqrt{\log M} \nearrow \infty.$$

3

Example (cont.)

Then

$$d_{\mathsf{TV}}(P,Q) = \frac{2\,p_1}{\sqrt{\log M}} \searrow 0$$

when $M \to \infty.$ On the other hand, for a sufficiently large M,

$$H(Q) - H(P) \approx p_1 \left(1 - \frac{L}{M}\right) \sqrt{\log M} \nearrow \infty.$$

Conclusion

It is easy to construct two random variables X and Y whose supports are finite although one of their supports is not bounded such that the total variation distance between their distributions is arbitrarily close to zero whereas the difference between their entropies is arbitrarily large. \Rightarrow If the alphabet size of X or Y is not bounded, then $d_{TV}(P_X, P_Y) \rightarrow 0$ does **NOT** imply that $|H(P_X) - H(P_Y)| \rightarrow 0$.

<ロ> (日) (日) (日) (日)

Can one get, under some conditions, a bound on the difference between the entropies in terms of the total variation distance ?

(4) (3) (4) (4) (4)

Can one get, under some conditions, a bound on the difference between the entropies in terms of the total variation distance ?

Answer 2

Yes, it is true when the alphabet sizes of X and Y are finite and <u>fixed</u>. The following theorem is an L_1 bound on the entropy (see [Cover and Thomas, Theorem 17.3.3] or [Csiszár and Körner, Lemma 2.7]):

Let P and Q be two probability mass functions on a finite set $\mathcal X$ such that

$$||P - Q||_1 \triangleq \sum_{x \in \mathcal{X}} |P(x) - Q(x)| \le \frac{1}{2}.$$

Then, the difference between their entropies to the base e satisfies

$$|H(P) - H(Q)| \le ||P - Q||_1 \log \left(\frac{|\mathcal{X}|}{||P - Q||_1}\right).$$

(4 間) トイヨト イヨト

Answer 2 (cont.)

This inequality can be written in the form

$$|H(P) - H(Q)| \le 2d_{\mathsf{TV}}(P,Q) \log\left(\frac{|\mathcal{X}|}{2d_{\mathsf{TV}}(P,Q)}\right)$$

when $d_{\mathsf{TV}}(P,Q) \leq \frac{1}{4}$, thus bounding the difference of the entropies in terms of the total variation distance when the alphabet sizes are finite and fixed.

Answer 2 (cont.)

This inequality can be written in the form

$$|H(P) - H(Q)| \le 2d_{\mathsf{TV}}(P,Q) \log\left(\frac{|\mathcal{X}|}{2d_{\mathsf{TV}}(P,Q)}\right)$$

when $d_{\mathsf{TV}}(P,Q) \leq \frac{1}{4}$, thus bounding the difference of the entropies in terms of the total variation distance when the alphabet sizes are finite and fixed.

Further Improvements of the Bound on the Entropy Difference in Terms of the Total Variation Distance

This inequality was further improved by S. Wai Ho & R. Yeung (see Theorem 6 and its refinement in Theorem 7 in their paper entitled "The interplay between entropy and variation distance," IEEE Trans. on Information Theory, Dec. 2010.)

- 4 間 5 - 4 三 5 - 4 三 5

Can one get a bound on the difference between the entropy H(W) and the entropy of the Poisson RV $Z \sim Po(\lambda)$ (with $\lambda = \sum p_i$) in terms of the bound on the total variation distance ?

同下 (三下 (三)

Can one get a bound on the difference between the entropy H(W) and the entropy of the Poisson RV $Z \sim Po(\lambda)$ (with $\lambda = \sum p_i$) in terms of the bound on the total variation distance ?

Answer 3

From the reply to the first question, since the Poisson distribution is defined over an infinitely countable set, it is not clear that the difference

 $H(W) - H(\mathsf{Po}(\lambda))$

can be bounded in terms of the total variation distance $d_{\text{TV}}(W, \text{Po}(\lambda))$. But, we provide an affirmative answer and derive such a bound.

< 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >

New Result (Answer 3 (cont.))

Let I be an arbitrary finite index set with $m \triangleq |I|$. Under the setting of this work and the notation used in slides 9–10, let

$$a(\lambda) \triangleq 2\left[\left(b_1 + b_2\right) \left(\frac{1 - e^{-\lambda}}{\lambda}\right) + b_3 \left(1 \wedge \frac{1.4}{\sqrt{\lambda}}\right) \right]$$
$$b(\lambda) \triangleq \left[\left(\lambda \log\left(\frac{e}{\lambda}\right)\right)_+ + \lambda^2 + \frac{6\log(2\pi) + 1}{12} \right] \exp\left\{ -\lambda - (m - 1)\log\left(\frac{m - 1}{\lambda e}\right) \right\}$$

where, in the last equality, $(x)_+ \triangleq \max\{x, 0\}$ for every $x \in \mathbb{R}$. Let $Z \sim \text{Po}(\lambda)$ be a Poisson random variable with mean λ . If $a(\lambda) \leq \frac{1}{2}$ and $\lambda \triangleq \sum_{\alpha \in I} p_{\alpha} \leq m - 1$, then the difference between the entropies (to the base e) of Z and W satisfies the following inequality:

$$|H(Z) - H(W)| \le a(\lambda) \log\left(\frac{m+2}{a(\lambda)}\right) + b(\lambda).$$

A Tighter Bound for Independent Summands

If the summands $\{X_\alpha\}_{\alpha\in I}$ are also independent, then

$$0 \le H(Z) - H(W) \le g(\underline{p}) \log\left(\frac{m+2}{g(\underline{p})}\right) + b(\lambda)$$

if $g(p) \leq \frac{1}{2}$ and $\lambda \leq m - 1$, where

$$g(\underline{p}) \triangleq 2\theta \min\left\{1 - e^{-\lambda}, \frac{3}{4e(1 - \sqrt{\theta})^{3/2}}\right\}$$
$$\underline{p} \triangleq \left\{p_{\alpha}\right\}_{\alpha \in I}, \quad \lambda \triangleq \sum_{\alpha \in I} p_{\alpha}$$
$$\theta \triangleq \frac{1}{\lambda} \sum_{\alpha \in I} p_{\alpha}^{2}.$$

The proof relies on the upper bounds on the total variation distance by Barbour and Hall (1984) and by Cekanavičius and Roos (2006), the maximum entropy result, and the derivation of the general bound.

How the entropy of the Poisson RV can be calculated efficiently ?

э

< 回 > < 三 > < 三 >

How the entropy of the Poisson RV can be calculated efficiently ?

Answer 4

The entropy of a random variable $Z \sim Po(\lambda)$ is equal to

$$H(Z) = \lambda \log\left(\frac{e}{\lambda}\right) + \sum_{k=1}^{\infty} \frac{\lambda^k e^{-\lambda} \log k!}{k!}$$

so the entropy of the Poisson distribution (in nats) is expressed in terms of an infinite series that has no closed form.

A D A D A A D A

Answer 4 (Cont.)

Sequences of simple upper and lower bounds on this entropy, which are asymptotically tight, were derived by Adell et al. [IEEE Trans. on IT, May 2010]. In particular, from Theorem 2 in this paper

$$-\frac{31}{24\lambda^2} - \frac{33}{20\lambda^3} - \frac{1}{20\lambda^4} \le H(Z) - \frac{1}{2}\log(2\pi e\lambda) + \frac{1}{12\lambda} \le \frac{5}{24\lambda^2} + \frac{1}{60\lambda^3}$$

which gives tight bounds on the entropy of $Z \sim \text{Po}(\lambda)$ for $\lambda \gg 1$.

- For $\lambda \ge 20$, the entropy of Z is approximated by the average of its above upper and lower bounds, asserting that the relative error of this approximation is less than 0.1% (and it scales like $\frac{1}{\lambda^2}$).
- For $\lambda \in (0, 20)$, a truncation of the above infinite series after its first $\lceil 10\lambda \rceil$ terms gives an accurate approximation.

イロト イポト イヨト イヨト

The setting of this problem was introduced by Arratia et al. (1989) in the context of applications of the Chen-Stein method.

The setting of this problem was introduced by Arratia et al. (1989) in the context of applications of the Chen-Stein method.

Problem Setting

 On the cube {0,1}ⁿ, assume that each of the n2ⁿ⁻¹ edges is assigned a random direction by tossing a fair coin.

The setting of this problem was introduced by Arratia et al. (1989) in the context of applications of the Chen-Stein method.

Problem Setting

- On the cube $\{0,1\}^n$, assume that each of the $n2^{n-1}$ edges is assigned a random direction by tossing a fair coin.
- Let k ∈ {0,1,...,n} be fixed, and denote by W ≜ W(k,n) the random variable that is equal to the number of vertices at which exactly k edges point outward (so k = 0 corresponds to the event where all n edges, from a certain vertex, point inward).

The setting of this problem was introduced by Arratia et al. (1989) in the context of applications of the Chen-Stein method.

Problem Setting

- On the cube $\{0,1\}^n$, assume that each of the $n2^{n-1}$ edges is assigned a random direction by tossing a fair coin.
- Let $k \in \{0, 1, ..., n\}$ be fixed, and denote by $W \triangleq W(k, n)$ the random variable that is equal to the number of vertices at which exactly k edges point outward (so k = 0 corresponds to the event where all n edges, from a certain vertex, point inward).
- Let I be the set of all 2^n vertices, and X_α be the indicator that vertex $\alpha \in I$ has exactly k of its edges directed outward. Then $W = \sum_{\alpha \in I} X_\alpha$ with $X_\alpha \sim \text{Bern}(p), \quad p = 2^{-n} \binom{n}{k}, \quad \forall \alpha \in I.$

The setting of this problem was introduced by Arratia et al. (1989) in the context of applications of the Chen-Stein method.

Problem Setting

- On the cube $\{0,1\}^n$, assume that each of the $n2^{n-1}$ edges is assigned a random direction by tossing a fair coin.
- Let $k \in \{0, 1, ..., n\}$ be fixed, and denote by $W \triangleq W(k, n)$ the random variable that is equal to the number of vertices at which exactly k edges point outward (so k = 0 corresponds to the event where all n edges, from a certain vertex, point inward).
- Let I be the set of all 2^n vertices, and X_α be the indicator that vertex $\alpha \in I$ has exactly k of its edges directed outward. Then $W = \sum_{\alpha \in I} X_\alpha$ with $X_\alpha \sim \text{Bern}(p), \quad p = 2^{-n} \binom{n}{k}, \quad \forall \alpha \in I.$
- <u>Problem</u>: Estimate the entropy H(W).

イロト 不得下 イヨト イヨト 二日

Example: Random Graphs (Cont.)

- The problem setting implies that $\lambda = \binom{n}{k}$ (since $|I| = 2^n$).
- The neighborhood of dependence of a vertex $\alpha \in I$, denoted by B_{α} , is the set of vertices that are directly connected to α (including α itself since it is required that $\alpha \in B_{\alpha}$). Hence, $b_1 = 2^{-n}(n+1){\binom{n}{k}}^2$.
- If α and β are two vertices that are connected by an edge, then a conditioning on the direction of this edge gives that

$$p_{\alpha,\beta} \triangleq \mathbb{E}(X_{\alpha}X_{\beta}) = 2^{2-2n} \binom{n-1}{k} \binom{n-1}{k-1}$$

for every $\alpha \in I$ and $\beta \in B_{\alpha} \setminus \{\alpha\}$, so by definition (see slide 10),

$$b_2 = n \, 2^{2-n} \binom{n-1}{k} \binom{n-1}{k-1}.$$

Example: Random Graphs (Cont.)

- b₃ = 0 (since the conditional expectation of X_α given (X_β)_{β∈I\B_α} is, similarly to the un-conditional expectation, equal to p_α). The directions of the edges outside the neighborhood of dependence of α are irrelevant to the directions of the edges connecting the vertex α.
- In the following, the bound on the entropy difference is applied to get a rigorous error bound on the Poisson approximation of the entropy H(W).
- By symmetry, the cases with W(k,n) and W(n-k,n) are equivalent, so

$$H(W(k,n)) = H(W(n-k,n)).$$

Numerical Results for the Example of Random Graphs

Table: Numerical results for the Poisson approximations of the entropy H(W) (W = W(k, n)) by the entropy H(Z) where $Z \sim Po(\lambda)$, jointly with the associated error bounds of these approximations. These error bounds are calculated from the new theorem (see slide 18).

n	k	$\lambda = \binom{n}{k}$	$H(W) \approx$	Maximal relative error
30	26	$2.741\cdot 10^4$	6.528 nats	0.94%
30	25	$1.425\cdot 10^5$	7.353 nats	4.33%
100	95	$7.529\cdot 10^7$	10.487 nats	$1.6 \cdot 10^{-19}$
100	85	$2.533\cdot 10^{17}$	21.456 nats	$2.6 \cdot 10^{-10}$
100	75	$2.425\cdot 10^{23}$	28.342 nats	$1.9\cdot 10^{-4}$
100	70	$2.937\cdot 10^{25}$	30.740 nats	2.1%

Generalization: Bounds on the Entropy for a Sum of Non-Negative, Integer-Valued and Bounded Random Variables

- A generalization of the earlier bound was derived in the full-paper version, considering the accuracy of the Poisson approximation for the entropy of a sum of non-negative, integer-valued and bounded random variables.
- This generalization is enabled via the combination of the proof of the previous bound, considering the entropy of the sum of Bernoulli random variables, with the approach of Serfling (Section 7 in his paper from 1978).

Full Paper Version

- This talk presents in part the first half of the paper:
 I. Sason, "An information-theoretic perspective of the Poisson approximation via the Chen-Stein method," submitted to the IEEE Trans. on Information Theory, June 2012. [Online]. Available: http://arxiv.org/abs/1206.6811.
- A generalization of the bounds that considers the accuracy of the Poisson approximation for the entropy of a sum of non-negative, integer-valued and bounded random variables is introduced in the full paper.
- The second part of this paper derives lower bounds on the total variation distance, relative entropy and other measures that are not covered in this talk.
